1 Introduction

PANACEA WP4 targets on the creation of a Corpus Acquisition and Annotation (CAA) subsystem for the acquisition and processing of monolingual and bilingual language resources (LRs) required in the PANACEA context.

This document focuses on the development and integration of the first version of the CAA subsystem in the PANACEA platform. This version incorporates a Corpus Acquisition Component (CAC) and a Cleanup and Normalization Component (CNC) as planned in Section 7 of D4.1 *Technologies and tools for corpus creation, normalization and annotation*. The present deliverable, together with D4.3, constitutes the second milestone of WP4.

We present the terminology used in this document in Section 2. The CAC and CNC modules and their deployment as web services are discussed in Section 3. In Section 4, we discuss some tools regarding the generation and presentation of the XML output of the services. Finally, we conclude and sketch future work in Section 5.

2 Terminology

This section defines common terminology used in the rest of this document.

*Corpus (or text corpus):* a (large) set of texts. In PANACEA, we assume the texts are stored electronically, in a given file format and character encoding, without any formatting information, eventually provided with metadata and/or linguistic annotation. Often, the texts are referred to as documents, in which case the texts are assumed to be topic-coherent.

*Monolingual corpus:* a corpus of texts in one language.

*Bilingual corpus:* a corpus of texts in two languages.

*Parallel corpus:* a bilingual corpus consisting of texts organized in pairs which are translations of each other, i.e. they include the same information (parallel texts). Usually, the pairs are identified at least for documents (parallel documents) and the corpus described as document-aligned parallel corpus. If the translation pairs are identified also for sentences (parallel sentences) we talk about sentence-aligned parallel corpus.

*Comparable corpus:* a bilingual corpus consisting of texts organized in pairs (comparable documents) which are only approximate translations of each other, i.e. they include similar information.

*Web Crawler:* a computer program that browses the World Wide Web in a methodical and automated manner in order to copy/store web documents (html pages, pdf documents, etc.) for later processing (e.g. indexing, creating corpora, etc.) In the initial version of the crawlers to be developed in WP4.1, the acquired corpora will consist only of html pages. In the context of this report, web documents, web pages and html pages are synonymous.

*Focused web crawler:* is a web crawler that downloads html pages that are relevant to a predefined topic in order to build topic-specific web collections. In the context of PANACEA,

---

1 Intellectual Property Rights issues are not discussed in this deliverable, as they are currently being handled in the context of WP2 Dissemination and Exploitation.
we aim to build a domain-specific crawler that will crawl for data on the automotive, legal and environment domains.

Seed pages: Web pages known to be relevant to a specific domain. A (focused) web crawler will be initialized with these pages.

3 Web services
This section describes the CAC and CNC modules and their deployment as web services ready to be integrated into the PANACEA platform. We present three tools and their corresponding services: the Focused Monolingual Crawler (FMC), the Focused Bilingual Crawler (FBC) and the boilerplate remover (BR). The requirements for the first version of the CAA subsystem, as reported in D7.1, are: i) Req-TEC-0101a (Components accessibility), ii) Req-TEC-0104 (Common interface compliant), iii) Req-TEC-0105 (Metadata description), iv) Req-TEC-0106 (Format compliant, v) Req-TEC-0108 (Error handling), vi) Req-TEC-0109 (Temporary data), vii) Req-TEC-1101 (Input/output proprietary data management) and viii) Req-TEC-0110 (Data Transfer). The crawling web services respect the initial design of the common interfaces in D3.1, in particular Section 9.2.7.2 Crawling.

3.1 Focused monolingual crawler
The FMC is the first module in the PANACEA pipeline for building LRs by crawling web documents with rich textual content. Its purpose is to adapt an efficient and distributed web crawling methodology that will collect web pages with content belonging to specific languages and predefined domains. The common strategy adopted by a general web crawler is to initialize the crawler by the seed pages, visit these pages and extract the links within them. Then new web pages are visited following the extracted links and so on. In focused crawling, a text to topic classifier is included in order to classify each page as relevant to the domain or not.

3.1.1 Mandatory and optional parameters
The FMC has been deployed as a web service in a Tomcat 6 web server hosting a Soaplab2\(^2\) web application accessible from http://sifnos.ilsp.gr:8888/soaplab2-axis/. The FMC is made available under the name ilsp_mono_crawl. The web interface of this tool is presented in fig. 1. It contains four mandatory parameters:

1. The Domain parameter corresponds to a descriptive title for the crawler’s job (e.g. LAB_EN_TEST_017). At this phase of the project, it also defines the name of a MySQL relational database that is created automatically, and in which the whole data (e.g. downloaded pages, extracted links, relevant scores, logs, etc.) are stored. It is worth mentioning that the Domain value may not be a mandatory parameter in the next version of the crawler, since the database name can be equivalent to the job name assigned automatically by the administrative framework of the PANACEA platform.

2. The LanguagesList is required for the definition of the targeted language. At this time supported languages are English, French, German, Greek, Italian and Spanish.

3. The TermList is a list of triplets (relevance weight, term, topic-class) that define the domain, as shown in Figure 1. Terms can be single words or phrases relevant to the domain.

---

\(^2\) Soaplab2, http://soaplab.sourceforge.net/soaplab2/, is a tool that can automatically generate and deploy web services on top of existing command-line analysis programs.
Weights are signed integers and indicate the relevance of the term with respect to the topic-classes. A score of relevance \( S \) for a web page is calculated by the following equation:

\[
S = \sum_{i=1}^{N} \sum_{j=1}^{4} n_{ij} \cdot w_i \cdot w_j
\]  

(1)

where \( N \) is the amount of terms in the topic definition, \( w_i \) is the weight of term \( i \), \( w_j \) is the weight of location \( j \) and \( n_{ij} \) denotes the number of occurrences of term \( i \) in location \( j \). The four discrete locations in a web page are title, metadata, keywords, and plain text. The corresponding weights for these locations are 10, 4, 2, and 1. If the score is greater than a predefined threshold, the web page will be classified as relevant to the specific domain.

For this version of the FMC, the predefined threshold is 90, while a default weight for a relevant term is 100. This implies that just one occurrence of a relevant term in a page results in classifying the page as relevant and, therefore, in guiding the FMC to extract and follow the links of the page. Higher or lower weights indicate more or less relevant terms, respectively. Negative values (e.g. \(-100\)) assigned to terms can be used to lower the scores of pages containing these terms.

Topic-classes are sub-categories of the targeted domain. For example, “working conditions” and “wages” could be two sub-classes of the “Labour Legislation” domain.

The topic definition can be provided as a URL which points to an appropriate file with term triplets. Alternatively, it can be provided as direct data by a user who can complete the corresponding field manually or upload an already existing file. The topic definition should contain one triplet per line and be encoded in UTF-8. An extract from a topic definition for “Environment” in English is provided below:

```
100: air pollution=environment_EN
100: biodiversity=environment_EN
100: climate change=environment_EN
```

More details about constructing such topic definitions are reported in Section 4.1 of D4.3. Moreover, some samples of topic definitions for the “Environment” and “Labour Legislation” domains in the languages targeted by PANACEA are included in the monolingual corpora of D4.3.

4. The \textit{UrlList} is a list of seed URLs with which the crawler is initialized. These URLs should be relevant to the domain (i.e. contain positively-weighted terms from the topic). Since the seed pages are assumed to be relevant, the crawler extracts their links and follows these links to visit/retrieve new pages. Similarly to the topic definition, the \textit{UrlList} can be provided as a URL, as direct data or as an existing file upload. The \textit{UrlList} should contain one URL per line. More details about constructing a list of seed URLs are reported in Section 4.2 of D4.3. Again, some samples of seed URLs for the “Environment” and “Labour Legislation” domains in the languages targeted by PANACEA are included in the monolingual corpora of D4.3.
There are also some optional parameters, which can be used to configure the crawl job. At this first version of the FMC, the optional parameters are:

1. **HarvestersNumber**: Defines the number of crawler threads to be used for a specific job. For example, if HarvestersNumber is defined to 5, five crawler threads will be working in parallel on the job. This parameter affects the performance of the job, since a simple way of increasing performance is to use more than one crawler for a job.

2. **MaxSize**: Indicates the maximum size of data (in MBs) that a job has to download. Therefore, the crawl job will stop after MaxSize MBs have been stored in the database. The default value is 1 MB. This option is disabled for users accessing the service via the Soaplab2 web application.

3. **MaxTime**: Indicates the maximum time (in minutes) that a crawl job has to run. Thus, the crawl job will stop after running for MaxTime minutes. The default value is 1. Users accessing the service via the web application can initiate crawl jobs lasting for 10 minutes maximum.

4. **Retries**: Defines the maximum number of http requests that a crawler will make in order to fetch a web document. If there is no response from the server after Retries times, the web document will be skipped. The default value is 10. This option is disabled for users accessing the service via the web application.

5. **Timeout**: Indicates the time (in seconds) that a crawler has to wait for a server’s response. The default value is 10 seconds. This option is disabled for users accessing the service via the web application.

6. **dropdb**: If set to true, this boolean parameter guides the module to delete the database schema of the crawl job after storing the results of the crawl in the filesystem. If false, the database schema is deleted after two days by a cron job.

7. **stay_in_web_domain**: If set to true, this boolean parameter guides the module to download data only from web domains in the UrlList. The true value is used mainly for demo purposes, while the default value is false.
3.1.2 Crawling for language- and domain-specific data

Following the solution path reported in Section 7.1 of D4.1, we adopted and modified the Combine crawler [Ardo, 2005] for this task. Combine incorporates modules which are required in focused crawling. Moreover, it is a modular and open-source tool that allows monitoring of the crawl progress by logging its actions in a relational database.

The first element in the pipeline of the crawl concerns the format detection and the conversion of character encoding to UTF-8. Based on the content_type header of the HTTP response, Combine detects the format of each visited web document. In this initial version of FMC, the crawler targets HTML pages only and discards documents in other formats. The next version of

---

3 http://combine.it.lth.se/documentation/
FMC will incorporate modules for converting other formats into a unified format (plain text). For encoding identification, Combine utilizes the content_charset header of the HTTP response, which indicates the character encoding of a visited web document. If needed, Combine employs the Encode Perl library\(^4\) to convert the encoding in UTF-8.

The second module in the pipeline is a language identifier. Lingua:Identify\(^5\), an open-source and flexible language identifier based on n-grams and implemented in Perl, is used for this task. As a result, documents that are not in the targeted language are discarded. Since Lingua:Identify did not support Greek, we contributed data to the tool developer, who generated a language fingerprint for Greek.

A significant element of the FMC is a text to topic classifier based on key terms or word n-grams. Such algorithms are widely used in web page classification [Qi and Davison, 2009]. Combine exploits a string-to-string matching algorithm for calculating a score of relevance for each visited page [Golub and Ardo, 2005]. In FMC, the score is calculated as described in 3.1.1 above. If this score overcomes a predefined threshold, the web page is classified as relevant to the domain and the HTML content of the web page is stored in the relational database. Then, the links within the stored page are extracted and the score of this page is assigned to these links. The crawler uses these links to visit new pages.

Combine, in its default implementation, extracts links only from pages that have been classified as relevant. In our initial experiments with FMC and in order to collect a lot of links for the process of the crawl, we set the threshold equal to 90, a relatively low value. Given that the weight of each term in our term lists was 100 (see Section 3.1.1), the selected value of the threshold was so low that even when a page contained just one relevant term, the page was considered relevant. In the next version of the FMC, we plan to combine the Best-First algorithm with the Tunnelling technique [D. Bergmark et al., 2002], as described in section 7 of D4.1. According to this technique, links will be extracted from both relevant and non-relevant pages, while only relevant pages will be stored.

One critical issue is the fact that Combine, in its current implementation, does not follow the most promising URLs (i.e. links within pages with high relevance to the domain), but considers the list of extracted URLs as a First-In First-Out (FIFO) queue. In other words, Combine employs the breadth-first algorithm [Pinkerton, 1994], which sorts the URLs to be visited with respect to the time they were extracted. It was proved [Dorado, 2008, Menczer et al., 2004] that Best-First [Cho et al., 1998] and InfoSpiders [Menczer and Belew, 2000] seem to be the most effective methods for focused crawling. Since InfoSpiders displays a disadvantage at the early stage of the crawling process (when the neural networks are not trained yet), we decided to exploit the Best-First algorithm and we modified Combine accordingly. The Best-First algorithm sorts the URLs with respect to their scores and selects a predefined number of the most promising URLs. In the next period of the project, we aim to introduce a method for estimating the number of the promising links instead of using a predefined number. Specifically, we plan to investigate (in cooperation with the ILSP team of the FP7 ICT ACCURAT project\(^6\)) if the adoption of an unsupervised machine learning method (like, for example, K-means

\(^4\) [http://search.cpan.org/dist/Encode/](http://search.cpan.org/dist/Encode/)

\(^5\) [http://search.cpan.org/~ambs/Lingua-Identify-0.26/README](http://search.cpan.org/~ambs/Lingua-Identify-0.26/README)

\(^6\) [http://www.accurat-project.eu/](http://www.accurat-project.eu/)
[MacQueen, 1967]) could be beneficial for classifying, the candidate URLs as “promising” or not.

The next processing step in the FMC pipeline concerns web page cleaning. For this task we integrated the Boilerplate tool (see also Section 3.3).

In order to improve the quality of the LRs delivered by the CAC to downstream tools and applications, a crawler should incorporate a stage for duplicate detection. Following the PANACEA Description of Work document, we will include a duplicate detection module in the second version of FMC (D4.4 due T21). In addition, we aim to integrate a dedicated web service for duplicate detection into the PANACEA platform.

The functionalities of the FMC are made available in the Soaplab2 server via a Soaplab2 ACD configuration file. The file, via which all mandatory and optional parameters mentioned above are defined, can be examined in Appendix C.

A workflow for the FMC has been developed and tested in the Taverna workflow management system\(^7\). Figure 2 presents the workflow with input ports for all mandatory and two optional (HarvestersNumber and MaxTime) parameters. The output of the FMC web service and workflow is a text file pointing to CesDoc documents with text segmented in paragraphs (c.f. Appendix A) and basic metadata as described in Section 6.1.3 of D3.1.

\(^7\) http://www.taverna.org.uk/
Figure 2 Focused monolingual crawler in Taverna
3.2 Focused bilingual crawler
The FBC is the first module in the PANACEA pipeline for building parallel LRs from the web. It aims to find multilingual websites and downloads web documents that are relevant to a predefined domain and in the targeted languages. At this initial version, the FBC starts from an initial URL, and in a spider-like mode finds the links within these pages pointing to pages inside the same web site, visits the new pages and so on. Therefore, FBC can be considered as a combination of a website copier (i.e. a tool that locally mirrors the structure of a web site), a text to topic classifier, and a module that extracts pairs of web documents in different languages.

The FBC has been deployed as a web-service accessible from the http://sifnos.ilsp.gr:8888/soaplab2-axis/ Soaplab2 web application under the name ilsp_bilingual_crawl. The Soaplab2 web interface of this tool is presented in Figure 3.

3.2.1 Mandatory and optional parameters
The FBC has common mandatory and optional parameters with the FMC (cf. Section 3.1.1 of this document). The main differences are that i) two languages are required (parameters Language1 and Language2), ii) the TermList has to include terms in both languages and iii) the UrlList must contain only one URL. This user-provided URL should point to a multilingual site.

3.2.2 Crawling for bilingual domain-specific data
The current version of FBC incorporates the same processing stages with FMC (cf. Section 3.1.2). The FBC follows links originating from the URL provided by the user, and it stores web pages relevant to the bilingual topic definition provided again by the user.

The bilingual topic definition should contain one triplet (< relevance weight, term, topic-class>) per line and be encoded in UTF-8. An extract from a bilingual topic definition for “Labour Legislation” in English and French is provided below:

```
100: collective agreement=LAB_EN_FR
100: work contract=LAB_EN_FR
100: trade union rights=LAB_EN_FR
100: trade union confederation=LAB_EN_FR
100: continuous working day=LAB_EN_FR
100: convention collective=LAB_EN_FR
100: contrat de travail=LAB_EN_FR
100: droits syndicaux=LAB_EN_FR
100: confédération syndicale=LAB_EN_FR
100: syndicat=LAB_EN_FR
100: journée continue=LAB_EN_FR
```

The following step of the FBC concerns examining the pool of stored HTML pages and deciding which pages can be considered as pairs from which parallel sentences can be extracted. Following the solution path reported in Section 7.2 of D4.1 we employed Bitextor\(^8\), for this task. Bitextor detects such pairs by exploiting a set of measures like: a) relative difference in file size, b) relative difference in length of plain text, c) edit distance of the HTML structures and d) edit

---

\(^8\) [http://sourceforge.net/projects/bitextor/](http://sourceforge.net/projects/bitextor/)
distance of the lists of numbers contained in the stored pages [Esplà-Gomis and Forcada, 2010].
In the next FBC version (D4.4 in T21) we aim to add measures concerning the relations of the
terms found in the documents (i.e. examining if the terms found in a document are translations
of the terms found in another document).

The functionalities of the FMC are made available in the Soaplab2 server via a Soaplab2 ACD
configuration file. The file, via which all mandatory and optional parameters are defined, can be
examined in Appendix D.
A workflow for the FBC has been developed and tested in the Taverna workflow management system\(^9\). Figure 4 presents the workflow with input ports for all mandatory and two optional (HarvestersNumber and MaxTime) parameters. The output of the FBC and its corresponding web service and workflow is a URL containing a list of links to cesAlign documents (see Appendix B for an example). Each cesAlign document points to a pair of cesDoc documents in the targeted languages.

\(^9\) http://www.taverna.org.uk/
Figure 4 Focused bilingual crawler in Taverna
3.3 Boilerplate remover

The BR aims to detect and remove boilerplate text that typically is not related to the main content (e.g. navigation links, advertisements, disclaimers, etc.) from a web document. For this task we employed the Boilerpipe\(^{10}\) tool which uses only a small set of shallow text features (e.g. number of words and link density) for classifying the individual text elements in a Web page [Kohlschütter et al., 2010]. Boilerpipe provides six methods for removing boilerplate (ArticleExtractor, ArticleSentencesExtractor, DefaultExtractor, KeepEverythingExtractor, LargestContentExtractor, NumWordsRulesExtractor). These methods either use different features or exploit different classification algorithms. Short descriptions of the methods are reported on http://boilerpipe.googlecode.com/svn/trunk/boilerpipe-core/javadoc/1.0/index.html.

The web-service of the BR is available in http://sifnos.ilsp.gr:8888/soaplab2-axis/ under the name boilerplate_remover. The web interface of this tool is illustrated in Figure 5. The input of the BR is a web document to be cleaned. The user can provide input as a URL or as an already stored file in HTML format. A method can be selected from MethodsList combo box. The default method is the third (DefaultExtractor). The output of the BR is the cleaned text file.

![Figure 5 The web interface of the boilerplate remover](image)

The functionalities of the BR are made available in the Soaplab2 server via a Soaplab2 ACD configuration file, which can be examined in Appendix E.

\(^{10}\)http://code.google.com/p/boilerpipe/
4 Traveling Object tools

This section discusses some tools regarding the generation and presentation of the XML output of the crawling services, which in PANACEA lingo is also called the Traveling Object. ILSP has developed a Java tool called FormatConverter that can convert data from and to the Traveling Object formats defined in D3.1. The FormatConverter tool uses the Factory Object-Oriented design pattern\(^\text{11}\), and consists of two interfaces to classes that can be sub-classed to cater for new input and output formats.

FormatConverter has been distributed among PANACEA partners, who have already extended and adapted it to their tools and web services (see, for example, D5.2 Section 3). For example, the tool has been integrated in the monolingual and bilingual pipelines, to take care of converting content and metadata extracted from crawled pages, to the “basic” version of the Traveling Object (D3.1, Section 6.1.2). The sample in Appendix A is an example of such a conversion.

ILSP has also developed an XSLT\(^\text{12}\) stylesheet for easy viewing of “basic” Traveling Object files. When such a file is loaded on a web browser, the current version of the stylesheet allows a user to examine the document’s metadata in a separate page (Figure 6), and copy the text of whole paragraphs to the clipboard (Figure 7).

\(^\text{11}\) http://en.wikipedia.org/wiki/Factory_method_pattern

\(^\text{12}\) http://www.w3.org/Style/XSL/
Conclusions and Workplan

In this deliverable we have documented the initial functional prototype of the CAA subsystem. This initial prototype consists of a web service for monolingual and a web service for bilingual focused web crawling. The two web services include modules for language identification and boilerplate removal. A third web service caters for boilerplate removal. The integration of these web services into the PANACEA platform complies with the PANACEA Description of Work document and the solution path detailed in D4.1.

The web services will be evaluated in WP7.2 Evaluation of the Integration of components. Based on the evaluation results we aim to implement a revised version of the CAA subsystem. This new version will integrate a web service for duplicate detection and the new version of the web service for boilerplate removal.

The PANACEA platform will also include NLP modules for all languages targeted by the project. In the context of the WP4.3 task, partners have already started adapting existing NLP tools and making them available as web services according to the functionalities and the timetable in D4.1, Table 8.

In more detail, the workplan for the CAA development in the context of WP4 will include the tasks sketched below:
• **T18: Internal deliverable.** All partners adapt NLP tools focusing on sentence splitting/tokenization and POS tagging/lemmatization for EN, DE, EL, ES, IT, FR. The I/O of all tools will be conformant with the common encoding format documented in *D3.1 Architecture and Design of the Platform*.

• **T21: D4.4.** 2nd version of the prototype and documentation. The revised prototype will integrate dedicated web services for normalization (including boilerplate removal and duplicate document detection), as required for *D7.3 Second evaluation report* (T22).

• **T22: Internal deliverable.** Partners adapt NLP tools focusing on parsing and/or chunking for DE, EN, EL, ES, IT, FR. The I/O of all tools will be conformant with the common encoding format documented in *D3.1 Architecture and Design of the Platform*. These tools will be part of the final version of the CAA subsystem.

• **T29: D4.5.** Final version of the prototype and documentation. The revised prototype will integrate NLP tools for a) sentence splitting/tokenization b) POS tagging/lemmatization and c) parsing for EN, DE, EL, ES, IT, FR, as required for *D7.4 Third evaluation report* (T30).

      <p id="p1">Glacial Retreat</p>
      <p id="p2">Glacial retreat: "With few exceptions, all the alpine glaciers of the world are losing mass and it is predicted that this trend will continue as global warming progresses. Glaciers in alpine areas act as buffers. During the rainy season, water is stored in the glaciers and the melt water helps maintain river systems during dry periods. An estimated 1.5 to 2 billion people
in Asia (Himalayan region) and in Europe (The Alps) and the Americas (Andes and Rocky Mountains) depend on river systems with glaciers inside their catchment areas. In areas where the glaciers are melting, river runoff will increase for a period before a sharp decline in runoff. Without the water from mountain glaciers, serious problems are inevitable and the UN’s Millennium Development Goals for fighting poverty and improving access to clean water will be jeopardized “United Nations Environment Programme, 2007 Global Outlook for Ice and Snow.”

Glacial retreat since 1850 has been worldwide and rapid, affecting the availability of fresh water for irrigation and domestic use, mountain recreation, animals and plants. These all depend on glacier-melt, and in the longer term and to some extent so does the level of the oceans.

Studied by glaciologists, the coincidence of glacial retreat with the measured increase of atmospheric greenhouse gases is evidence underpinning anthropogenic climate change. Mid-latitude mountain ranges such as the Himalayas, Alps, Rocky Mountains, Cascade Range, Glacier National Park, and the southern Andes. This is also occurring in tropical glacier summits such as Mount Kilimanjaro in Africa, and Chacaltaya Glacier in Bolivia which are showing some of the largest proportionate glacial loss.

The Little Ice Age was a period from about 1550 to 1850 when the world experienced relatively cool temperatures compared to the present. Subsequently, until about 1940 glaciers around the world retreated as the climate warmed. Glacial retreat slowed and even reversed, in many cases, between 1950 and 1980 as a slight global cooling occurred. However, since 1980 a significant global warming has led to glacier retreat becoming increasingly rapid and ubiquitous, so much so that many glaciers have disappeared and the existence of a great number of the remaining glaciers of the world is threatened.

In locations such as the Andes of South America and Himalayas in Asia, the demise of glaciers in these regions will have potential impact on water supplies, and flooding from ‘mountain tsunamis’. The retreat of mountain glaciers, notably in western North America, Asia, the Alps, Indonesia and Africa, and tropical and subtropical regions of South America, has been used to provide qualitative evidence for the rise in global temperatures since the late 19th century. The recent substantial retreat and an acceleration of the rate of retreat since 1995 of a number of key outlet glaciers of the Greenland and West Antarctic ice sheets foreshadow a rise in sea level, having a potentially dramatic effect on coastal regions worldwide.

The continued glacial retreat will have a number of different quantitative impacts. In areas that are heavily dependent on water runoff from glaciers that melt during the warmer summer months, a continuation of the current retreat will eventually deplete the glacial ice and substantially reduce or eliminate runoff. A reduction in runoff will affect the ability to irrigate crops and will reduce summer stream flows necessary to keep dams and reservoirs replenished. This situation is particularly acute for irrigation in South America, where numerous artificial lakes are filled almost exclusively by glacier melt.

Central Asian countries have also been historically dependent on the seasonal glacier melt water for irrigation and drinking supplies. In Norway, the Alps, and the Pacific Northwest of North America, glacier runoff is important for hydropower.

The potential for major sea level rise depends mostly on a significant melting of the polar ice caps of Greenland and Antarctica, as this is where the vast majority of glacial ice is located.
