1  
2  
3 Sir,

4  
5  
6 Pentavalent antimonials (meglumine antimoniate, Glucantime® and sodium  
7  
8 stibogluconate, Pentostam®) are the gold standard therapy for cutaneous  
9  
10 leishmaniasis. Intralesional (IL) therapy is usually the treatment of choice for localized  
11  
12 cutaneous disease, whereas intramuscular (IM) and intravenous treatment are  
13  
14 recommended for extensive forms and for cases involving the mucosal surfaces.

15  
16 Cutaneous Adverse Drug Reactions (CADRs) to IM Glucantime® have been reported  
17  
18 in less than 1% of the patients.<sup>1-4</sup> They occur more frequently after IL administration,  
19  
20 being described in about 3% of over 1000 reported cases.<sup>2-9</sup> These comprise both type-  
21  
22 I and type-IV allergic reactions. We report two cases of cutaneous reactions to  
23  
24 Glucantime® in two patients diagnosed and treated at Hospital del Mar, Barcelona,  
25  
26 that illustrate the clinical and pathogenic heterogeneity of this uncommon side effect.

27  
28 Case 1: A 35-year-old Caucasian man suffering from ankylosing spondylitis and  
29  
30 Crohn's disease and receiving treatment with subcutaneous adalimumab fortnightly  
31  
32 developed a small ulcer on the right lower leg one week after a mosquito bite while on  
33  
34 vacation in Sri Lanka in February 2013. The patient spent the preceding months in  
35  
36 Portugal. Diagnosis of cutaneous leishmaniasis was confirmed by identification of  
37  
38 *Leishmania infantum* in cutaneous tissue through molecular techniques. Sri Lanka is  
39  
40 known to be endemic for *L. donovani*<sup>10</sup>, but considering the clinical history it is very  
41  
42 likely that the infection was acquired there. Treatment with adalimumab was stopped  
43  
44 and weekly IL Glucantime® (meglumine antimoniate 1500mg/mL, Sanofi-Aventis,  
45  
46 France; excipient: potassium metabisulfite) was administered. Few minutes after the  
47  
48 third administration, the patient developed erythema, edema and pruritus at the  
49  
50 injection site; emesis, dizziness and widespread urticarial lesions (Fig.1) developed  
51  
52 after the seventh injection. After presenting this clinical picture the treatment was  
53  
54 withdrawn. The cutaneous ulcer showed progressive resolution without any additional  
55  
56 treatment. Prick tests and immediate intradermal reaction were positive to meglumine  
57  
58 antimoniate (Fig.2a,b). A 4-millimeter punch biopsy obtained from the resulting  
59  
60 erythematous papule 48 hours after intradermal infiltration was compatible with  
hypersensitivity reaction.

1  
2  
3 Case 2: A 47-year-old Caucasian woman with a personal history of positive serology  
4 for hepatitis C virus, developed a solitary ulcerated plaque on the left leg while  
5 travelling in Brazil, one month after starting the vacation. The ulcer progressively  
6 enlarged and new ulcers appeared in a sporotrichoid distribution. *Leishmania*  
7  
8 *panamensis* was identified in cutaneous tissue confirming the diagnosis of cutaneous  
9 leishmaniasis. The patient denied any lesions prior to departure and did not recall any  
10 mosquito bite on that area while in Barcelona, where she usually lives. The causal  
11 relationship strongly suggests that the infection was acquired in Brazil. Daily IM  
12 Glucantime® 20mg/Kg was started in October 2014. During the second week of  
13 treatment the patient developed subcutaneous nodules on the injection site, headache  
14 and nausea. Treatment was switched to intravenous administration, and after the  
15 fourteenth perfusion, self-limited acute generalized urticaria developed. This was  
16 suggestive of type-I hypersensitivity, but prick tests and immediate intradermal  
17 reaction with meglumine antimoniate 1% were negative. However, the intradermal  
18 reaction was positive after 48h, in favor of delayed type-IV hypersensitivity.  
19 Treatment was switched to intravenous pentamidine isethionate with favorable  
20 evolution.  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30  
31

32  
33 Two different subsets of cutaneous hypersensitivity reactions to Glucantime® have  
34 been reported in the literature. Immediate reactions range from localized and  
35 generalized urticaria with or without systemic symptoms to anaphylactic shock and  
36 probably represent type-I Ig-E-mediated allergic reactions. This was the case of our  
37 first patient, who developed immediate urticaria with systemic symptoms. Positive  
38 prick test and immediate intradermal reaction confirmed type-I hypersensitivity  
39 mechanism.  
40  
41  
42  
43

44 Delayed reactions include eczematous lesions and persistent subcutaneous nodules,  
45 probably resulting from type-IV allergic reactions. Our second patient developed  
46 persistent subcutaneous nodules at the injection sites and had positive delayed  
47 intradermal test, which favors a type IV-hypersensitivity mechanism.  
48  
49  
50

51 Cordoba and co-workers<sup>5</sup> performed intradermal reaction, prick and patch tests in 7  
52 patients who developed eczema at IL Glucantime® injection site. Intradermal reaction  
53 with Glucantime® as is and diluted was positive in all 7 patients, whereas prick tests  
54 were negative in all of them and patch tests positive in one. No other study reports the  
55 use of additional tests to confirm mechanism behind the observed cutaneous lesions.  
56  
57  
58  
59  
60

CARDs to IL Glucantime® might have different clinical presentations depending on the underlying mechanisms. Despite their rarity, the recognition and confirmation of such reactions is important in order to discontinue treatment in due time and prevent further complications.
